

Question 14

Natural Language Processing (NLP) is a branch of AI that gives computers the ability to understand, interpret and generate human language

- Real world examples are

- (a) Predictive text when writing an email or message
- The NLP model analyses the context of a message or previously used words to suggest a prediction
- (b) Siri voice assistant understands the intent behind words and act accordingly
- (c) Google translate uses NLP to understand the syntax and context of text in one language and generate an accurate translation in another language

Question 15

A Large Language Model (LLM) is an advanced AI system that is trained on large datasets to understand, generate and interact with human language

They differ from standard ML models by that these are designed to perform one specific task whereas LLM handle multiple tasks

Examples are

- (a) Chat Gpt - used to generate emails, content, debug compilers and general brainstorming
- (b) Gemini AI - has advanced reasoning capabilities to understand and generate text, code, images and audio.
