

algorithms

- For example student data

### Semi-structured data

- It is information that does not reside in a rigid relational database format but still contains tags, marks or metadata to separate semantic elements and enforce hierarchies
- Offers flexibility to use revolving data for example web apps

### Unstructured data

- It is data that has a complex format and does not have a fixed schema
- It does not contain a predefined format and is more complex and requires special skills to analyse
- For example data from Facebook, twitter or audio files
- It is mainly used in natural language processing and generative AI.

### Question 6

- Data modeling is the process of creating visual representations to communicate connections between data points using either all the information system or part of it.
- It is important because it illustrates the type of data used and stored within a system and it also describes how the data is grouped and organised as well as the relationships between the data
- The types of data models that will be explained further are conceptual, logical and physical data models.
