

Question 9

- ETL (Extract, Transform, Load) is a data integration process that extracts data from different sources, cleans and organises it into a single dataset that is consistent for example a data warehouse or a data lake.

a) Extract Stage

- During this stage, data is moved from different sources such as SQL servers, emails, webpages to a staging area.

b) Transform

- At this stage, also known as the staging area, raw data is processed. It is transformed and consolidated for its intended use case.

- This process includes filtering, cleansing, aggregating, de-duplicating, validating and authenticating data.

- The ETL process is important in data analytics because it ensures that clean data is readily available in the data warehouse for advanced analytics.
